FluencyTracr Measurement Model

What Glean collects on its own vs. what Fluency Tracker derives for aggregate AI fluency measurement

Clean boundary: Glean logs events. Fluency Tracker interprets aggregate behavior. Data Science validates whether the interpretation is credible.

Already in Glean

1. Glean collects on its own

WORKFLOW_RUN
workflow, agent, step, action status; app and run IDs

Assistant / Chat
sessions, citations, feedback, joins to workflow runs

Search / Retrieval
searches, clicks, retrieved documents, source engagement

Agent / MCP / Security
tool use, errors, policy events; export and governance may vary

Product snapshots
daily inventory of workflows, actions, action packs, subscriptions

Raw event exhaust and metadata. Not a fluency model by itself.

Fluency Tracker layer

2. Fluency Tracker adds

Signal readiness map
availability, scrub status, join keys, completeness

Trace reconstruction
ordered starts, steps, retries, failures, checks, completions

Behavioral proxies
exposure, calibration, friction, recovery, capability growth

Safety gates
missingness, ambiguity, k-min cohort, privacy suppression

Evidence output
aggregate fluency dimensions, confidence level, trend narrative

This is the measurement layer: interpretation, not collection.

DS validation

3. Data Science validates

Construct validity
does the proxy mean what we claim?

Proxy confidence
coverage, stability, drift, threshold sensitivity

Missingness audit
which orgs/windows/features are computable or suppressed

Outcome calibration
compare signal movement to enablement and business context

Guardrail review
avoid person-level, productivity, team-ranking, or causal claims

Validate credibility before this becomes a score.

How the passive behaviors map

Behavior family	Glean source signal	Fluency Tracker interpretation
Adoption / exposure	WorkflowRun, Chat, AI Answer, Product Snapshot	Which AI surfaces are becoming part of regular work
Verification / calibration	Citations, citation clicks, Search/Retrieval, feedback	Whether users ground, check, or challenge AI output
Friction / recovery	Step status, errors, latency, retries, abandoned runs	Where AI workflows break, recover, or need enablement
Capability growth	Agents, actions, MCP usage, reusable workflow/app IDs	Movement from simple use to repeatable higher-value workflows
Responsible use	AI Security / policy events where approved	Governance-safe aggregate risk and oversight patterns

Clean claim: Glean collects behavioral telemetry. Fluency Tracker converts it into aggregate, validated fluency evidence. Anything thin, ambiguous, or privacy-sensitive is suppressed.

Do not claim: individual performance, productivity, team rankings, raw content quality, ROI, or causal impact from logs alone.
